▼ Question 1: <u>Correct</u>	
How many keys are used with asymmetric (public key) cryptography	y?
One	
Two	
Three	
○ Four	
Explanation	
Public key (asymmetric) cryptography uses two keys: one is referred the private key. This key pair overcomes the difficulties associated we keys. The communicating parties do not need to share secret informations shared. Public keys are associated with users through authentication, directory, such as a certificate authority. The sender transmits a confirmation public key. The message can only be decrypted with the a solely by the recipient. Public key cryptography not only provides enauthentication technologies such as digital signatures.	with the secure distribution of private ation; only the public keys are , usually through a mutually trusted idential message using only the associated private key possessed

▼ Question 2: <u>Correct</u>	
A receiver wants to verify the integrity of a message received from a within the digital signature of the sender.	a sender. A hashing value is contained
Which of the following must the receiver use to access the hashing variansmission?	value and verify the integrity of the
Receiver's public key	
Sender's public key	
Sender's private key	
Receiver's private key	

Explanation

Digital signatures are created using the sender's private key. Thus, only the sender's public key can be used to verify and open any data encrypted with the sender's private key. The recipient's private and public keys are not involved in this type of cryptography situation. Often, the hashing value of a message 1/28/2020 TestOut LabSim

is protected by the sender's private key (their digital signature). The recipient must extract the original References

Question 3: Incorrect	
Which of the following are characteristics of ECC? (Select two.)	
Uses multiplication of large prime numbers	
Symmetric encryption	
Asymmetric encryption	
Uses a finite set of values within an algebraic field	
Explanation	
<i>Elliptic curve cryptography</i> (ECC) is an approach to cryptography that uses a finite set of values within an elliptic curve (an algebraic set of numbers). ECC is an asymmetric encryption algorithm.	1
RSA is an asymmetric algorithm that uses the multiplication of large prime numbers for encryption. References

Question 4: Incorrect	
Which of the following algorithms are used in asymmetric encryption? (Select two.)	
Twofish	
Blowfish	
RSA	
AES AES	
Diffie-Hellman	
Explanation	
RSA and Diffie-Hellman are asymmetric algorithms. RSA, one of the earliest encryption algorithms, coalso be used for digital signatures. The Diffie-Hellman protocol was created in 1976, but is still in use today in technologies such as SSL, SSH, and IPsec.	æ

Question 5: <u>Incorrect</u>	
Which form of asymmetric cryptography is based upon Diffie-Hellman?	
→ C El Gamal	
○ ECC	
■ RSA	
Merkle-Hellman Knapsack	

Explanation

1/28/2020 TestOut LabSim

El Gamal is based upon Diffie-Hellman.

▼ Question 6:

Incorrect

Which cryptography system generates encryption keys that could be used with DES, AES, IDEA, RC5, or any other symmetric cryptography solution?

Merkle-Hellman Knapsack

Diffie-Hellman

○ RSA

Elliptical Curve

Explanation

Diffie-Hellman is the only key generation system in this list of options. Diffie-Hellman produces a number that can be used as a key in any symmetric cryptography solution (assuming the number is within the algorithm's keyspace).

Merkle-Hellman Knapsack is not a key generation system. Instead, it is an insecure concept that predates public key encryption. Elliptical curve is not a key generation system. Instead, it is a method of applying other systems to gain greater strength from smaller keys. RSA is not a key generation system. Instead, it is an asymmetric cryptography system that can be used for encryption, key exchange, and digital signatures.

▼ Question 7:

Incorrect

Match each public key cryptography key management mechanism on the left with the corresponding description on the right. Each mechanism may be used once, more than once, or not at all.

Implements the Diffie-Hellman key exchange protocol using elliptic curve cryptography

Exist only for the lifetime of a specific communication session

Uses no deterministic algorithm when generating public keys

Perfect forward secrecy

Can be reused by multiple communication sessions

Explanation

Public key cryptography can use a variety of mechanisms to manage encryption keys, including the following:

- *Ephemeral keys* are generated every time the key establishment process is executed and only exist for the lifetime of a specific communication session. As such, these keys have a relatively short lifespan.
- *Static keys* can be reused by multiple communication sessions. As such, these keys remain in use for a relatively long period of time.
- *Perfect forward secrecy* can be implemented in public key cryptography system so that random public keys are generated for each session. No deterministic algorithm is used when generating the

1/28/2020 TestOut LabSim

public keys.

• *Elliptic curve Diffie-Hellman* (ECDH) is an implementation of the Diffie-Hellman key exchange protocol using elliptic curve cryptography. It allows two parties, each having their own elliptic curve public/private key pair, to generate symmetric keys simultaneously over a non-secure channel.

▼ Question 8: Correct

Above all else, what must be protected to maintain the security and benefit of an asymmetric cryptographic solution, especially if it is widely used for digital certificates?

Hash values
Public keys
Cryptographic algorithm

Private keys

Explanation

The strength of an asymmetric cryptographic system lies in the secrecy and security of its private keys. A digital certificate and a digital signature are little more than unique applications of a private key. If the private keys are compromised for a single user, for a secured network, or for a digital certificate authority, the entire realm of trust is destroyed.

▼ Question 9:

Incorrect

Which of the following is used in conjunction with a local security authority to generate the private and public key pair used in asymmetric cryptography?

CPS

OCSP

CRL

CSP CSP

O CA

Explanation

A cryptographic service provider (CSP) resides on the client and generates the key pair. This is a software program that can generate keys using a specific algorithm.

The certificate authority (CA) is an entity trusted to issue, store, and revoke digital certificates. The certificate practice statement (CPS) is a declaration of the security that the organization is implementing for all certificates issued by the CA holding the CPS.

The certificate revocation list (CRL) resides in the CA and consists of a list of certificates that have been previously revoked. The online certificate status protocol (OCSP) is a protocol used for checking the status of an individual digital certificate to verify whether it is good or has been revoked.

▼ Question 10:

<u>Correct</u>

3/2020	TestOut LabSim
Mary wants to send a the message?	message to Sam so that only Sam can read it. Which key would be used to encrypt
Sam's public	c key
Sam's priva	te key
Mary's publ	ic key
Explanation	
Use Sam's public key can be used to decryp	to encrypt the message. Only the corresponding private key, which only Sam has, \ensuremath{t} the message.
key can be decrypted that anyone could rea	's private key because only Sam has that key. Anything encrypted with the private by anyone with the public key. Encrypting using Mary's private key would mean d the data using Mary's public key. Encrypting with Mary's public key would mean be able to decrypt it using her private key.

LabSim for Security I [All Questions SecPro	Pro, Section 9.6. p2017_v6.exm ASYM_ENCRYPT_08]
Question 12:	Correct
The success of asymm	netric encryption is dependent upon which of the following?
The secrecy	of the algorithm
The comple	xity of the cipher text

Explanation

The secrecy of the key

 $\hfill \bigcirc$ The integrity of the individuals who created the cryptosystem

1/28/2020 TestOut LabSim

The strength of an asymmetric encryption system lies in the secrecy and security of its private keys. The strength of a cryptosystem should not be in the secrecy of the algorithm. This means that the algorithm is usually published and can be scrutinized for weaknesses.
